ServiceNow Workflow Automation

Platform	ServiceNow / Workflow Studio
Flow	Auto Classify School Tickets
Trigger	Incident WorkFlow Created
Core actions	Conditional Flow Logic + Update Record
Validation	Completed test run with incident record INC0001007

This document is prepared from the supplied ServiceNow screenshots and the structure of the reference project documentation. The screenshots in the reference document have been replaced with the four project screenshots supplied for this project.

1. Introduction

1.1 Project Overview

Auto Ticket Classification using Flow Designer is a ServiceNow workflow automation project that demonstrates how an incident record can be evaluated through conditional flow logic and updated automatically. The implemented flow is named Auto Classify School Tickets and is shown in Workflow Studio.

The supplied execution screenshot shows an Incident WorkFlow Created trigger followed by conditional branches. The first branch is labelled If SD is Wifi or Network and contains an Update Record action. A second branch is labelled Else If SD is Projector or Hardware and also contains an Update Record action.

1.2 Objective

- To create an incident-based automation flow in ServiceNow Workflow Studio.
- To trigger the automation when an Incident WorkFlow record is created.
- To evaluate the incident using conditional flow logic.
- To use Update Record actions for the matching classification paths.
- To test the flow and verify that the execution completes successfully.

1.3 Project Outcome

The supplied execution evidence shows the test run completed successfully. The first conditional branch was evaluated as True and its Update Record action completed. The alternative branch was not run in that execution.

1.4 Technologies and Components Used

Component	Purpose / Evidence

ServiceNow Workflow Studio	Builds and executes the Auto Classify School Tickets flow.
Incident WorkFlow Created	Trigger shown at the beginning of the execution.
Conditional Flow Logic	Evaluates the incident against the configured SD conditions.
Update Record	Core action used in the classification branches.
Incident WorkFlow table	Custom table shown with name u_incident_workflow.
Project Update Set	Completed update set used for the project configuration.

2. Problem Statement and Proposed Solution

2.1 Problem Statement

Incident records can contain different types of issues. When classification depends entirely on manual checking, the process can be inconsistent and may require repeated user effort. A rule-based Flow Designer process can evaluate the incident and apply the appropriate update path.

2.2 Proposed Solution

The project uses ServiceNow Workflow Studio to automate incident classification. When an Incident WorkFlow record is created, the flow evaluates the configured conditions. If the first condition is satisfied, its Update Record action runs. If that condition is not satisfied, the flow can evaluate the alternative branch for projector or hardware-related descriptions.

2.3 Process Flow

1. An Incident WorkFlow record is created.
2. The Auto Classify School Tickets flow starts from the Incident WorkFlow Created trigger.
3. The flow evaluates the condition labelled “If SD is Wifi or Network”.
4. If the condition is true, the corresponding Update Record action executes.
5. Otherwise, the Else If branch for “Projector or Hardware” can be evaluated.
6. The flow execution result can be reviewed in Execution Details.

2.4 Scope

- Incident creation trigger and workflow execution.
- Conditional classification logic for the labels shown in the supplied flow.
- Update Record actions in the configured branches.
- Validation using the supplied incident record and execution details.

2.5 Out of Scope

- The supplied screenshots do not establish external notification, email, asset, vendor, or inventoryintegrations.
- The screenshots do not show the exact field values written by each Update Record action.

3. Implementation

3.1 Create the Flow

1. Open Workflow Studio in the ServiceNow instance.
2. Create/open the flow named “Auto Classify School Tickets”.
3. Configure the Incident WorkFlow Created trigger.
4. Add conditional flow logic for the classification rules.
5. Add Update Record actions to the required branches.

3.2 Configure the Trigger

The supplied execution screenshot explicitly shows the trigger as Incident WorkFlow Created. The execution is shown as running under System Administrator and reaching the Completed state.

3.3 Configure the Classification Logic

The first visible branch is labelled If SD is Wifi or Network. Its flow logic is evaluated as True in the supplied test run, and its Update Record action is shown as Completed. The next branch is labelled Else If SD is Projector or Hardware; it is shown as Not Run for this particular execution.

3.4 Incident Record Used for Validation

The supplied incident screenshot shows record INC0001007. The visible fields include Caller “Abraham Lincoln”, Category “Network”, Subcategory “Wi-Fi”, and Short Description “Network Issue”. The screenshot is used as evidence of the incident data involved in the test.

3.5 Update Set and Table Configuration

The project update set screenshot shows Project Update Set in the Global application with State set to Complete. The custom table screenshot shows the label Incident WorkFlow, table name u_incident_workflow, Global application, and 15 table columns.

Project Screenshots

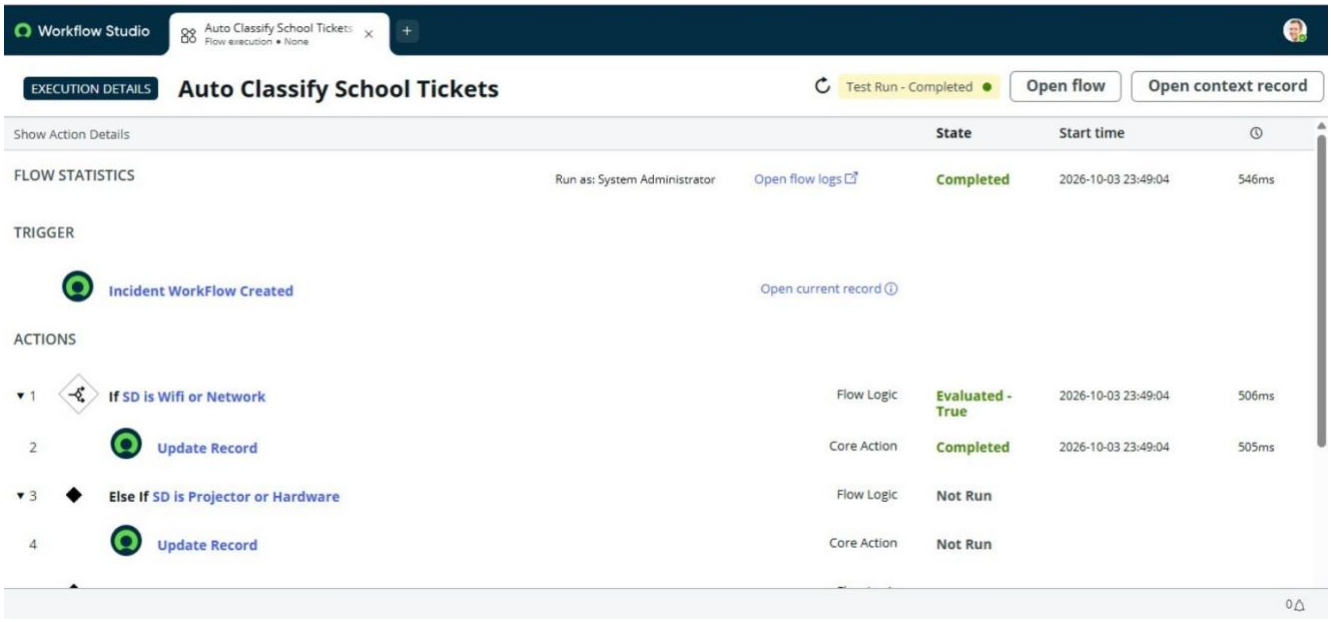

Figure 1. Auto Classify School Tickets – completed execution details.

Evidence: the test run is Completed; Incident WorkFlow Created is the trigger; the Wifi or Network branch evaluated True and its Update Record action completed.

Project Screenshots

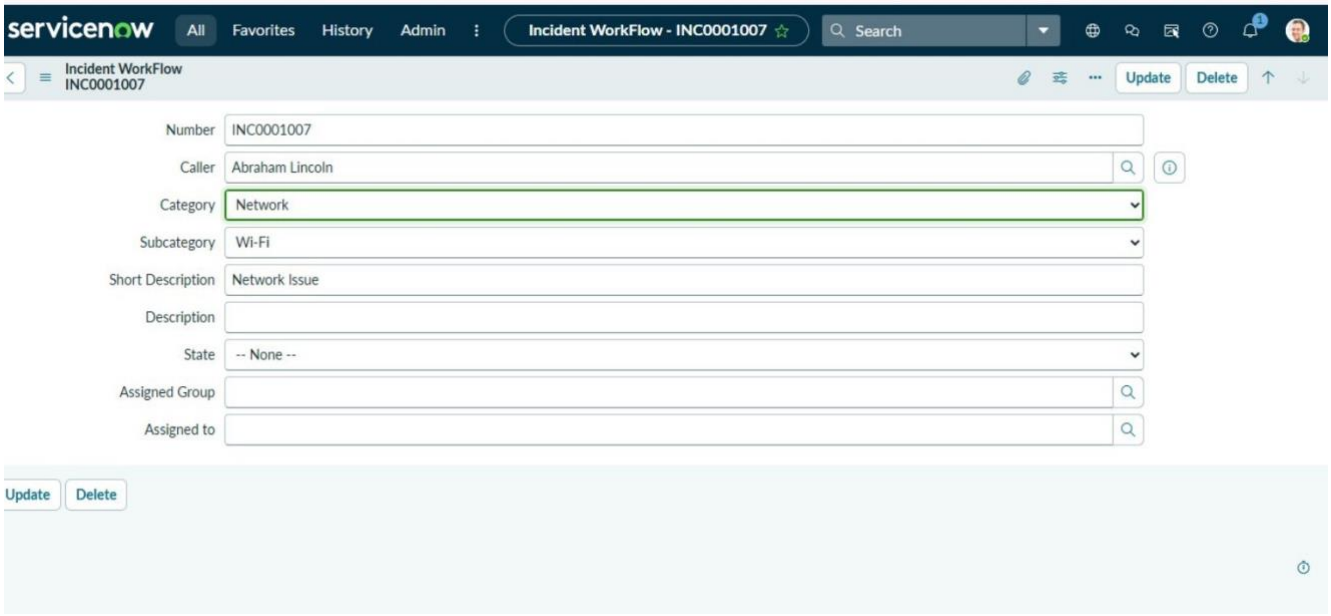

Figure 2. Incident WorkFlow record INC0001007 used in the project test.

Visible values: Category = Network, Subcategory = Wi-Fi, Short Description = Network Issue.

Project Screenshots

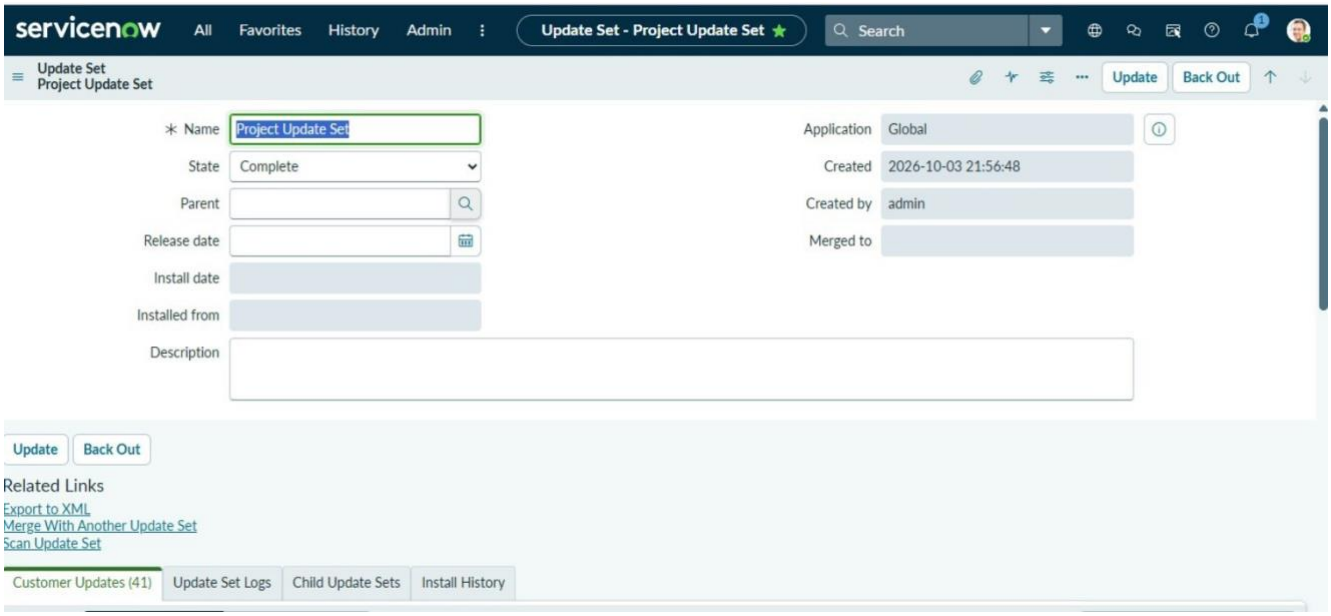

Figure 3. Project Update Set configuration.

Visible evidence: Name = Project Update Set, State = Complete, Application = Global, Created by = admin.

Project Screenshots

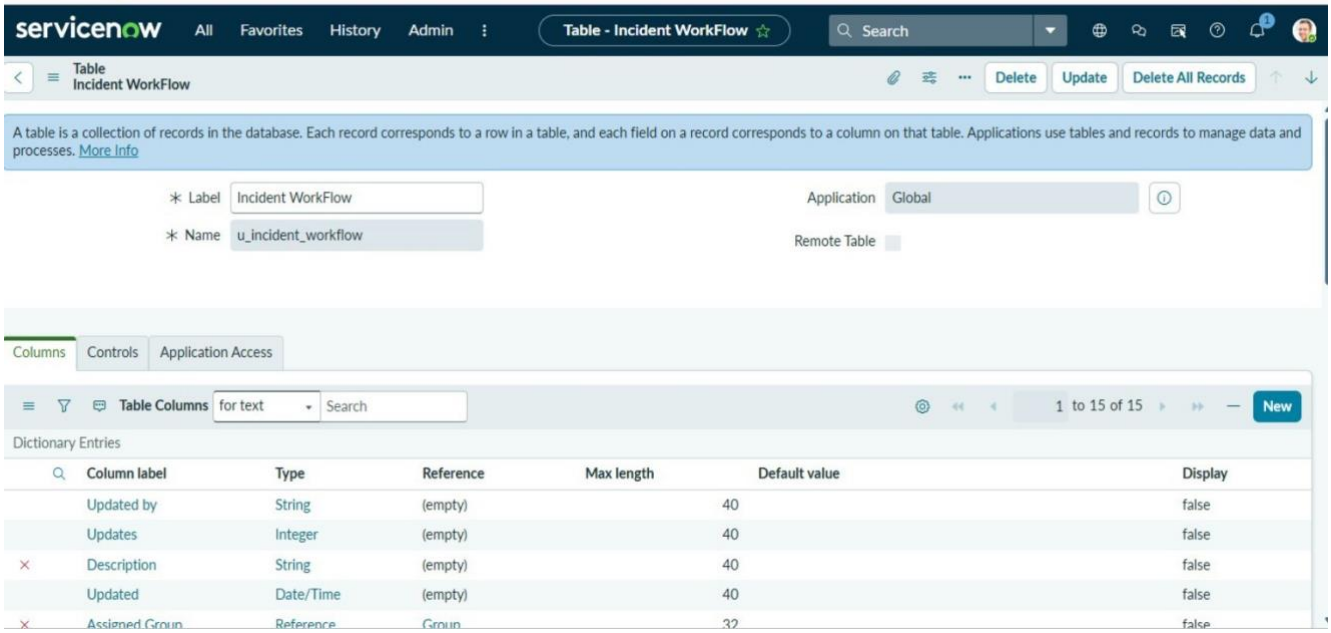

Figure 4. Incident WorkFlow custom table definition.

Visible evidence: Label = Incident WorkFlow, Name = u_incident_workflow, Application = Global, and 15 table columns.

4. Testing and Validation

4.1 Test Case 1 – Flow Execution

Expected: the Auto Classify School Tickets flow executes from the Incident WorkFlow Created trigger and reaches a completed state. Observed: the supplied execution screenshot shows the overall state as Completed.

4.2 Test Case 2 – Conditional Branch Evaluation

Expected: the configured condition is evaluated and the matching branch runs. Observed: “If SD is Wifi or Network” is Evaluated - True and its Update Record action is Completed. The alternative Projector or Hardware branch is Not Run in this test.

4.3 Test Case 3 – Incident Record Verification

Expected: a valid incident record is available for the workflow test. Observed: incident INC0001007 is shown with Network category, Wi-Fi subcategory, and Network Issue as the short description.

4.4 Test Case 4 – Configuration Evidence

Expected: project configuration is captured in an update set and the workflow table exists. Observed: Project Update Set is Complete, and the Incident WorkFlow table is shown as u_incident_workflow with 15 columns.

Test	Expected	Observed	Status
T1	Flow completes	Execution state = Completed	Pass
T2	Matching condition runs	Wifi or Network = Evaluated - True; Update Record = Completed	Pass
T3	Incident data available	INC0001007 with Network / Wi-Fi / Network Issue	Pass
T4	Configuration recorded	Project Update Set = Complete; table = u_incident_workflow	Pass

5. Benefits, Limitations and Future Enhancements

5.1 Benefits

- Reduces repeated manual classification effort for the configured incident conditions.
- Provides a consistent rule-based classification path.
- Makes the workflow execution visible through Execution Details.
- Uses Update Record actions to automate record updates.
- Provides a foundation for adding more classification conditions and actions.

5.2 Limitations of the Demonstrated Scope

- The supplied screenshots show the branch labels and execution results, but not the exact fieldmappings inside each Update Record action.
- The supplied evidence does not show downstream notifications, integrations, or external systems.
- Only the displayed test execution is validated; the alternative branch is shown as Not Run in thatexecution.

5.3 Future Enhancements

- Add more ticket categories and keywords to improve classification coverage.
- Add additional Update Record mappings for each ticket type.
- Add notifications or assignment rules after classification.
- Add more test cases for projector, hardware, and other ticket types.

6. Conclusion

The Auto Ticket Classification using Flow Designer project demonstrates a ServiceNow workflow that responds to an Incident WorkFlow Created event and evaluates the incident using conditional logic. In the supplied test execution, the Wifi or Network condition evaluated True and the corresponding Update Record action completed successfully. The incident record, update set, and custom table screenshots provide supporting configuration evidence.

7. Key Learnings

- How to create and execute a flow in ServiceNow Workflow Studio.
- How an incident-created trigger can start an automation.
- How conditional branches can be used to classify incident records.
- How Update Record actions can be placed under classification branches.
- How Execution Details can be used to validate flow status and branch results.
- How a custom table and update set can support the project configuration.

Appendix A – Demonstrated Configuration Summary

Configuration Item	Value shown in supplied project screenshots
Project Title	Auto Ticket Classification using Flow Designer
Flow Name	Auto Classify School Tickets
Trigger	Incident WorkFlow Created
First Condition	If SD is Wifi or Network
First Action	Update Record
Alternative Condition	Else If SD is Projector or Hardware
Alternative Action	Update Record
Test Run State	Completed
Incident Record	INC0001007
Category	Network
Subcategory	Wi-Fi
Short Description	Network Issue
Update Set	Project Update Set
Update Set State	Complete
Custom Table Label	Incident WorkFlow
Custom Table Name	u_incident_workflow
Table Columns	15

Source note: all project-specific facts in this document are based on the supplied reference documentation and the four screenshots supplied with this request. Where a screenshot does not expose an internal configuration value, the document does not claim a specific value.
